

## More cardiac arrest victims could survive with dispatcher CPR instruction, rescue breaths for children

November 7, 2017 in Medicine & Health / Cardiology

More people will survive cardiac arrest if emergency medical dispatchers give chest compression-only CPR instructions over the phone and if infants and children receive chest compressions with rescue breaths, according to updated CPR guidelines published today by the American Heart Association (Association), the world's leading voluntary health organization devoted to fighting cardiovascular disease.

The changes in the 2017 American Heart Association Focused Updates on Adult and Pediatric Basic Life Support and Cardiopulmonary Resuscitation Quality also re-emphasize the importance of bystanders starting immediate [chest compressions](#) if they see an adult collapse in a suspected cardiac arrest. Immediate bystander help has been shown to double or triple survival chances among the more than 350,000 Americans who suffer out-of-hospital cardiac arrest each year.

Highlighting the need for rapid response, the 2017 Focused Updates stress the importance of providing dispatch-assisted compression-only CPR instructions when cardiac arrest is suspected. Telephone CPR not only assists the untrained caller, but it reminds the CPR-trained caller how to provide high-quality CPR in a stressful situation. Currently, only half of the nation's dispatchers provide telephone CPR, which has been identified as a critical intervention in the chain of survival for out-of-hospital cardiac arrest.

The 2017 Focused Updates were informed by research published since the 2015 Guidelines Update, and authors found even more evidence supporting the need for compressions and rescue breaths during CPR for children who have not yet reached puberty. More than 7,000 children die from an out-of-hospital [cardiac arrest](#) annually. In most cases, it is the result of a lack of oxygen, and rescue breaths can keep oxygenated blood flowing through the system.

"The 2017 Focused Updates validate what we already know about performing CPR and offer a scientific basis for optimizing CPR quality to save more lives," said Karl Kern, M.D., chair of the Association's Emergency Cardiovascular Care Committee and professor of medicine at the University of Arizona College of Medicine - Tucson's Sarver Heart Center. "It's critically important to translate new science to bedside care as quickly as possible, especially as the amount of scientific research available is growing rapidly."

The Guidelines had previously been updated every five years, and this marks the first year that the International Liaison Committee on Resuscitation (ILCOR), an organization of global resuscitation experts, is switching to an annual format. The Association represents the United States on the committee.

The ILCOR evaluation process involves hundreds of resuscitation scientists and experts worldwide, who evaluate thousands of peer-reviewed publications for high-priority resuscitation topics requiring a systematic review. The annual focused update allows the rigor of a comprehensive review and expert consensus in as close to real time as possible.

"A continuous evidence evaluation process means that we can address new science quickly and recommend when it should change care," said Robert Neumar, M.D., Ph.D., past chair of the Association's Emergency Cardiovascular Care Committee, current ILCOR co-chair, and professor and chair of the Department of Emergency Medicine at the University of Michigan. "In this day and age of rapid-fire digital distribution and

fewer fact checks, it also allows us to refute studies that may not demonstrate a need to change current practices."

Since establishing its Guidelines in 1966, the Association has led evaluation and dissemination of the latest resuscitation science to help inform and modernize CPR. These guidelines have been used to train more than 22 million people annually in CPR, cardiovascular care and first aid around the world.
